The conditions of the field positions are measured using a commercialized available hand-held shade measurement tool for solar site assessments (SunEye 210 Shade Tool, Solmetric). Equipped with fisheye lens camera, compass, GPS and shading identifying image processing software, this tool provides shading patterns, annual sun paths and monthly solar access, etc. Below (Figure 2) a solar access chart of one particularly site is shown.

Figure 2: Solar access chart provided by the SunEye tool.

3.2 Parts Characterization

In order to accurately determine the performance of a particular park lamp product, the product is disassembled and each part is characterized in details so the performance can be estimated by interpolation of data points.

A typical park light system consists of a small PV module in the range 0.5-5 Wp, an electronic controller managing the charging of the battery and managing the power flow to the LED, a battery and a LED. Each of these 4 components is characterized in dedicated labs under different load conditions.

For the PV part IV-curves is recorded under 10-15 different illuminations, all AM 1.5 varying from .05 Sun till 1.2 Sun, and the full IV-curves is put into the simulation since it turns out that far from all charge controllers have maximum power point trackers. The IV curves are plotted in Figure 3 with the current on the left and the sun intensity on the right, which should be read at the left axis intersection – i.e. at the short circuit current.

Figure 3: IV-curves.

Figure 4: Example of concluded results from a characterization measurement of a LED light source in one of the purchased park lamps.

Included in the work of validating the model is characterizing the different components of the park lamps purchased, as briefly mentioned above. Figure 4 shows some concluded results of one of the park lamps LED light source, after being measured in the lab. Besides the quality of the light, such as Correlated Color Temperature (CCT) and Color Rendering Index (CRI), parameters related to the efficiency of the light source are being measured, such as total luminous flux, efficacy and total radiant flux. All these parameters are possible inputs in the model, which will make it possible to investigate the potential of improvements associated with different available products.

3.3 Field measurement

A few Park lights were put onto to our test side, equipped with data logging in order to determine the energy flow in the system with reference to a pyranometer (Kipp & Zonen SMP3-I) installed nearby. Since typically the PV is voltage controlled, measuring the current in the PV loop requires special attention. Measuring the current by measuring a voltage drop over a resistor, gives an additional voltage drop in the loop and perturbs the control of the PV. Choosing a resistive current measurement, the resistor should be chosen to be as small as possible, however large enough to provide good resolution to the data logger. Therefore a current sensor that senses without introducing a voltage drop in the loop is preferred; however these are expensive for the relevant current range. Another alternative is to improve the resolution by amplifying the voltage over the measurement resistor. For the data logging in this system the current is measured via a very small resistor limiting the resolution on the current measurements. The cumulative energy flow for few selected days is plotted in Figure 5, with the zero being arbitrary. The data is recorded close to fall equinox and therefore it is to be expected that there is energy enough for the night to light the LED, as can be seen as a straight blue line. For this product the size of the battery around 6 AH, however the charge controller seems to continue charging even though the battery is full, and thereby degrading the battery.

Figure 5: Energy gain for a few days in septemeber. The starting point is arbitrary chosen and the battery was not empty.

4 FUTURE WORK

The next step forward in this project is to collect measurements on the electronic controller and the batteries that will enable to simulate the behavior of the chosen park light and later on validate the model by comparing the simulated behavior with the actual measured behavior.

The resolution on the current measurement on the field testing will be improved and generic models that describe system behavior via datasheet information will be developed.

Parallel to the modeling work prototypes of park lights will be demonstrated where both dedicated power electronics, PV and LEDs will be chosen and combined with intelligent dimming control. The total system electronic efficiency is expected to be above 80 %.

5 CONCLUSION

We have demonstrated important building blocks to facilitate a powerful dimensioning tool and partial validated it to existing product. Measurement on existing products shows a lot can be done by upgrading the performance of the electronics.

6 AKNOWLEDGEMENTS

The project is funded by the Danish Energy Technology Development and Demonstration Programme, project number 64011-0323, "The PV LED Engine - new generation of intelligent solar powered LED lighting".
